Remarks. The sourceArray and destinationArray parameters must have the same number of dimensions. In addition, destinationArray must already have been dimensioned and must have a sufficient number of elements to accommodate the copied data. When copying between multidimensional arrays, the array behaves like a long one-dimensional array, where the rows (or columns) are conceptually laid end to ...

Even though this post is four years old, I was curious about this and ran some tests. The most important thing to note is that a coder should ALWAYS declare a variable as SOMETHING. Undeclared variables clearly performed the worst (undeclared are technically Variant). Long did perform the fastest, so I have to think that Microsoft's recommendation to always use Long instead of Integer makes sense.

column that is indexed. On a side note, if you have such field and it is the primary key, there is no performance penalty for using order by versus select max(id). The primary key is how data is ordered in the database files (for InnoDB at least), and the RDBMS knows where that data ...

Coefficient vector, specified as a real vector or real array. The coefficient vector represents the objective function  $f^*x$ . The notation assumes that  $f$  is a column vector, but you are free to use a row vector or array. Internally, `linprog` converts  $f$  to the column vector  $f(:)$ . If you specify  $f = []$ , `intlinprog` tries to find a feasible point without trying to minimize an objective function.

Note: Prior to PostgreSQL 7.4, the precision in float(p) was taken to mean so many decimal digits. This has been corrected to match the SQL standard, which specifies that the precision is measured in binary digits. The assumption that real and double precision have exactly 24 and 53 bits in the mantissa respectively is correct for IEEE-standard floating point implementations.
